CORRECT ENGLISH—HOW TO USE IT! A monthly magazine devoted to the use of English. Josephine Truck House, Editor.

Partial Contents: Queries and Answers, Shall and Will: Should and Would, How to use them, Pronunciations (Century Dict.), Correct English in the Home, Correct English in the School, What to say and what not to say, Course in Grammar, Course in letter writing, and Punctuation.

Business English for the business Man, Compound Words: How to write them, Studies in English Literature, Agents Wanted, \$1.00 a year. Send 10 cents for sample copy.

CORRECT ENGLISH, Eva Stout, Editor.

NOTICE: I am appointed deputy to ...

T. P. Sellers, Attorney-at-Law, Practices in the Parishes of St. John and St. Charles and Jefferson.

PROPER STORAGE WILL SAVE SWEET POTATOES

VALUE OF CROP OFTEN DECREASED BY CARELESS METHODS OF HANDLING.

STORE IN WELL BUILT HOUSE

An Abandoned Tenant House Can Very Often Be Utilized For This Purpose.

Improper methods of harvesting and storing sweet potatoes are responsible for large losses which greatly decrease the value of the crop, according to A. F. Kidder, professor of agronomy, Louisiana State University.

- Some of the things to be observed are as follows: 1. Potatoes should be thoroughly mature before being harvested. 2. They should be handled carefully to prevent bruises, as such places cause rot very quickly. 3. Injured potatoes should not be stored with sound ones. 4. The potatoes should be subjected to a temperature of 85 to 95 degrees Fahrenheit as soon as they are put away, and the moisture content reduced to 10 per cent or less. 5. Potatoes should be stored in a well built house, where the temperature can be kept uniform.

DISPOSE OF THE UNPROFITABLE HEN

Culling Should Be Done Frequently and Thoroughly.

After hens reach a certain age, depending upon the way they have been handled, they can no longer produce eggs profitably. Those which are forced for heavy egg production by the liberal use of stimulants will reach this stage quicker than the others.

A pretty safe rule to follow with the average flocks which have not been treated with stimulants is as follows: Dispose of hens of the light, active breeds, such as Leghorns and Anconas, as soon as they have passed through their third laying season; and dispose of the medium weight breeds, such as Plymouth Rocks, Rhode Island Reds, Wyandottes and Orpingtons as soon as they have passed through two laying seasons.

The culling should be done frequently and thoroughly. It rarely pays to hold an old or a weak bird for a better market. The quicker they are sold the better. The average flock should be thoroughly culled at least once a month.

OATS YIELD WELL FOLLOWING LEGUMES

Some examples of successful oat production in different parts of Louisiana where the crop was planted on lands that had grown a leguminous crop the previous summer are given below. In each case the land was broken to a depth of from six to ten inches and then thoroughly disked and harrowed.

In the Red River valley, near Shreveport, a 40-acre field of oats grown on land that had been in alfalfa for four years yielded 84 bushels per acre. Two bushels of acclimated Texas red-rust-proof oats per acre were drilled October 15.

In the Ouachita River valley, near Monroe, 50 bushels of oats per acre were produced on land that had been in lespedeza. Two and one-half bushels of Louisiana red-rust-proof oats per acre were drilled October 15.

INFERIOR SEED MAY CAUSE CROP FAILURE

OFTEN CONTAIN OBNOXIOUS WEED SEED THAT CAUSE PERMANENT INJURY TO FARM.

SEED WILL BE TESTED FREE

There is No Necessity For the Louisiana Farmer To Plant Seed of Unknown Value.

One of the essential features of profitable crop production is the use of good seed. The farmer of Louisiana has often suffered inadequate returns and, no doubt, in some instances complete crop failure owing to the use of seed of inferior grade.

There is no necessity for the Louisiana farmer to plant seed of unknown value. A seed testing laboratory is maintained at the Experiment Station of the Louisiana State University for the purpose of furnishing information to farmers and seedsmen as to the quality of commercial agricultural seeds.

To secure a sample, take three or four handfuls of clover or grass seed or ten or twelve tablespoonfuls of larger seeds. The sample must represent accurately the bulk from which it is taken.

WATCH FOR THE SWEET POTATO BORER

Because of the increased acreage of sweet potatoes in Louisiana this year, there is a serious danger that the sweet potato weevil or borer, will become distributed over a large area.

Send the samples to the Seed Laboratory, Experiment Station, Louisiana State University, Baton Rouge. No charge is made for the tests.

REMEDY FOR PLANT LICE ON GREENS

Turnips, mustard and radishes grown in Louisiana during the fall months are often severely injured by a small, light green, scabbed, sucking insect—an aphid, or plant louse—that is found principally on the underside of the leaves.

These aphids may be kept under control by spraying with a mixture of one teaspoonful of nicotine sulphate and an inch cube of kerosene soap in a gallon of water.

REMEDY FOR PLANT LICE ON GREENS

These aphids may be kept under control by spraying with a mixture of one teaspoonful of nicotine sulphate and an inch cube of kerosene soap in a gallon of water.

To facilitate spraying the seed should be planted in drills or rows of broadcast. It is also much easier to reach the aphids on plants having smooth leaves.

Display posters advocating the planting of a large acreage in oats and a limited acreage in wheat, have been distributed over the state by the Extension Division of the Louisiana State University.

14-DAY DIPPING MEANS PROMPT ERADICATION

THE STATE CAN BE MADE ENTIRELY TICK-FREE IN ONE SEASON.

EVERYONE MUST CO-OPERATE

Louisiana is the Only State Using the Twenty-one Day Dipping Periods.

Some of the questions most frequently asked on tick eradication are answered below by Dr. W. H. Jones, chief, of the Department of Veterinary Science, Louisiana State University.

Why is it necessary to dip every 14 days during the season to get rid of the ticks? Answer: During the warm months of the year, the average tick develops from the egg to the adult stage in about 14 days. But while 22 days may be the average, many ticks mature in less than that time.

How has this information been obtained? Answer: It has been obtained by a series of experiments conducted by the Louisiana State University during the season, under the supervision of Dr. W. H. Jones.

How long will it take to clean a parish or portion of the state of the 14-day and 21-day dipping periods? Answer: With the full cooperation of everyone interested, the tick may be eradicated in one season.

DO TICKS HAVE ANY EFFECT ON OAT PRODUCTION?

Answer: Federal entomologists have conducted this question and have shown that ticks which bite on a horse or cow have killed him in some cases, but that ticks which bite on a horse or cow have not been shown to have any effect on oat production.

Will the development of heat in the soil during the summer months affect the development of heat in the soil during the winter months? Answer: No.

THE BEST OF THE GOOD ONES.

All the experiments of the Government food experts and the athletic members of Yale University prove that Quaker Oats are the strongest and healthiest.

What is a condition of tick freedom expected to mean to the state? Answer: It will mean that Louisiana will be in a position to progress agriculturally and otherwise, as the more progressive states have done that have been free from the debilitating effects of a general quarantine, on account of Texas or tick fever, and the presence of cattle ticks, which is surely worth consideration.

Display posters advocating the planting of a large acreage in oats and a limited acreage in wheat, have been distributed over the state by the Extension Division of the Louisiana State University.
