What is the Difference that Causes It to Grow?

Like a thief at night in a dark room, causing symptoms of a common cold, the virus infects the body, reproducing itself and spreading without the host's knowledge.

The virus enters through the nose or mouth, attaching to specific receptors on the cells. It then replicates and spreads, infecting more cells. The immune system responds by producing antibodies to fight the infection. The symptoms, such as coughing, sneezing, and runny nose, are the body's way of fighting the virus.

The virus is contagious, spreading through respiratory droplets or by touching contaminated surfaces. Prevention includes washing hands frequently, covering the mouth and nose when coughing or sneezing, and avoiding close contact with people who are sick.

In the end, it's a matter of managing the symptoms and allowing the body to fight off the infection. With proper hygiene and measures, we can reduce the spread and prevent the virus from causing further damage.
