HEATING FROM NATURAL GAS.
Great Progress Has Been Made in Vehicles for Radiating Warmth.
When natural gas was first employed for heating dwellings, several years ago, the devices for adapting it to stoves and grates were very crude, and the amount of gas consumed was correspondingly extravagant. The end of the pipe—often half an inch to an inch—was run into the stove or grate, a perforated iron burner was fitted upon it at right angles, and the cavity filled with broken fire brick, slag from the glass furnaces, doorknobs of porcelain, balls of fireclay, or other substances that would radiate a great deal of heat.
Frequently the bits of broken brick were whitewashed, as were the back and side walls of the grates, or they were artistically done in water colors, the gas flames neither smoking the one nor burning off the other. After a time fireclay was molded into imitations of logs of wood, the cut ends of the logs, the cracks and knots and the bark with moss on it being imitated so successfully that the results could scarcely be told from the real back logs of olden times.
These imitation logs were placed on large brass additons, and when the flames were seen issuing from fissures the illusion was complete to the sense of sight, and to the sense of feeling too, for while "one side roasted the other side froze," as used to be said of attempts at keeping warm by the fireplaces of our grandfathers.
A year ago it began to be noticed that the supply of gas was diminishing. People woke up on cold mornings to find only a sickly blue flame languishing at the bottom of the grate or stove where once had been a roaring furnace. They were assured that there was plenty of gas; that some temporary obstruction in the pipes had caused the shortage, and all would soon be right.
And all was right as soon as the weather became warmer; but presently the gas companies were insisting that consumers should burn gas by meter, instead of paying so much for each fire and consuming all they pleased. This initiated the economic stage of natural gas use.
Inventors set their wits to work, and soon the market was flooded with all sorts of devices for getting the largest amount of heat from a minimum consumption of gas. The deep set back walls of the fireplaces built for coal were moved out, and the throats of the chimneys stopped up.
Various metal heaters with reflecting surfaces and draughts arranged on scientific principles were made to set into the fireplaces, until a fire that formerly required from 100 to 150 feet of gas an hour could be made to do the same service with a consumption of but fifteen feet. When the price of gas was raised from ten cents to fifteen cents per thousand feet in Pittsburgh, thousands of economic gas grates, ranges and stoves were sold during the first cold spell.
One of the cheapest and most cheerful devices now in use is an adaptation of asbestos to firebacks and radiating surface. A heavy cardboard, coated with asbestos, is perforated with rows of holes, from which are suspended fringes of skein asbestos, which becomes incandescent in the flame, and gives forth a beautiful, scintillating glow which imparts great cheerfulness to the apartment and at the same time radiates considerable heat.
But by far the most economical thing is a small sheet iron stove not much larger than a man's silk hat. This is lined with copper and sometimes filled with asbestos filler, and is connected with the supply pipe by means of gum hose, so that it can be set in the middle of the room or near the wall, as may be desired. One such stove, consuming no more gas than an ordinary ranged burner, will heat a medium sized room to a comfortable temperature and reduce gas bills to proportions correspondingly comfortable.—Youth's Companion.

Take Notice.
